

601.220 Intermediate Programming

Summer 2022, Meeting 16 (July 15th)

Today's agenda

- Review exercise 27
- Day 28 recap questions
- Exercise 28

Reminders/Announcements

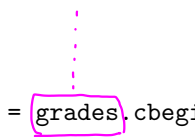

- HW6 is due **Friday, April 7th** by 11 pm
 - Written homework, note late submissions

Exercise 27 review

Part 2: mean and median functions

```
double GradeList::mean() {  
    assert(!grades.empty());  
    double sum = 0.0;  
    for (std::vector<double>::const_iterator i = grades.cbegin();  
         i != grades.cend();  
         ++i) {  
        sum += *i;  
    }  
    return sum / grades.size();  
}
```

this → grades

```
double GradeList::median() {  
    return percentile(50.0);  
}
```

percentile

this → percentile

Exercise 27 review

Part 3: in main2.cpp:

```
GradeList gl;
```

```
double min_so_far = 100.0;
for (size_t i = 0; i < gl.grades.size(); i++) {
    if (gl.grades[i] < min_so_far) {
        min_so_far = gl.grades[i];
    }
}
```

This does not work because `grades` is a private member of `GradeList`, so a `main` function (which is not a member of `GradeList`) cannot access it directly.

Exercise 27 review

Part 3: one possible solution is

```
// in grade_list.h (adding new public member functions)
```

```
size_t get_num_grades() const { return grades.size(); }  
double get_grade(size_t i) const { return grades[i]; }
```

```
// in main2.cpp
```

```
double min_so_far = 100.0;  
for (size_t i = 0; i < gl.get_num_grades(); i++) {  
    if (gl.get_grade(i) < min_so_far) {  
        min_so_far = gl.get_grade(i);  
    }  
}
```

Exercise 27 review

Another possible solution: add to `grade_list.h` (in `GradeList` class)

```
const std::vector<double> &get_grades() const  
{ return grades; }
```

In `main2.cpp`, change `g1.grades` to `g1.get_grades()`.

Arguably, this doesn't violate encapsulation because a `const` reference can't be used to modify the internal data of the `GradeList` object. However, it does result in "leaking" the knowledge that the grades in a `GradeList` are stored in a `std::vector<double>`.

Exercise 27 review

```
// Part 4 (main3.cpp)
#include <iostream>
#include "grade_list.h"

int main() {
    GradeList gl;
    for (int i = 0; i <= 100; i += 2) {
        gl.add(double(i));
    }
    std::cout << "Minimum: " << gl.percentile(0.0) << std::endl;
    std::cout << "Maximum: " << gl.percentile(100.0) << std::endl;
    std::cout << "Median: " << gl.median() << std::endl;
    std::cout << "Mean: " << gl.mean() << std::endl;
    std::cout << "75th percentile: " << gl.percentile(75.0) << std::endl;
}
```

Day 28 recap questions

- ➊ What is a non-default (or “alternative”) constructor?
- ➋ If we define a non-default constructor, will C++ generate an implicitly defined default constructor?
- ➌ When do we use the `this` keyword?
- ➍ What is a destructor?
- ➎ A destructor will automatically release memories that are allocated in the constructor- true or false?

1. What is a non-default (or “alternative”) constructor?

A non-default constructor has one or more parameters. Usually, these are used to initialize the field(s) of the object being initialized.

Example:

```
class Point {  
private:  
    double x, y;  
public:  
    Point() : x(0.0), y(0.0) { }    // default constructor  
    Point(double x, double y)      // non-default constructor  
        : x(x), y(y) { }  
    // ... other member functions ...  
};
```

2. If we define a non-default constructor, will C++ generate an implicitly defined default constructor?

No. For example:

```
class Point {  
private:  
    double x, y;  
public:  
    Point(double x, double y)  
        : x(x), y(y) { }  
    // ... other member functions ...  
};
```

```
// ...elsewhere...
```

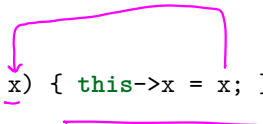

```
 Point p; // will not compile
```

3. When do we use the `this` keyword?

The `this` keyword is useful for explicitly referring to the object a member function is called on, sometimes called the “receiver” object. It is a *pointer* to the receiver object.

Among other uses, `this` can be useful for disambiguating a member variable that has the same name as a parameter. Example:

```
class Point {  
private:  
    double x, y;  
public:  
    // ...  
    void set_x(double x) { this->x = x; }  
    // ...  
};
```

4. What is a destructor?

A `class` (or `struct`) type's destructor member function is called automatically when an object's lifetime ends. Its purpose is to deallocate any dynamic resources associated with the object.

Examples of dynamic resources:

- dynamically allocated memory
- file resources not automatically closed by a destructor

Destructor example

```
class CBuf {  
private:  
    char *buf;  
    size_t size;  
  
public:  
    CBuf(size_t sz) : buf(new char[sz]), size(sz) { }  
    ~CBuf() { delete[] buf; }  
  
    // ...other member functions...  
};
```

5. A destructor will automatically release memories that are allocated in the constructor- true or false?

False.

The destructor must *explicitly* deallocate dynamically-allocated memory using either `delete` or `delete[]` (depending on whether or not the memory being deallocated is an array.)

Exercise 28

- `grade_list` again, but this time storing grades in a dynamically allocated array
 - This is very much like how `std::vector` works!
- Talk to us if you have questions!
